Motivation

- Cross-border bank claims have grown markedly over the past two decades.
- For a few advanced economies, banks' cross-border claims are currently as large as outstanding domestic bank credit to the non-bank sector.
- The purpose of this paper is to analyze the main determinants of cross-border bank flows, especially the factors driving the supply of cross-border bank credit.
- In particular, we study the effect of monetary policy on these flows.

Contribution

- We identify changes in banks' supply of cross-border credit due to the monetary policy stance of the domestic central bank using dyadic data.
- Evaluate the importance of country-specific monetary policy, as opposed to global factors, in determining bank flows (Bruno and Shin, 2014; Cerutti, Claessens and Ratnovski, 2014).
- Identify and novel channel of domestic monetary policy on foreign credit.

Data and estimation setup: This study

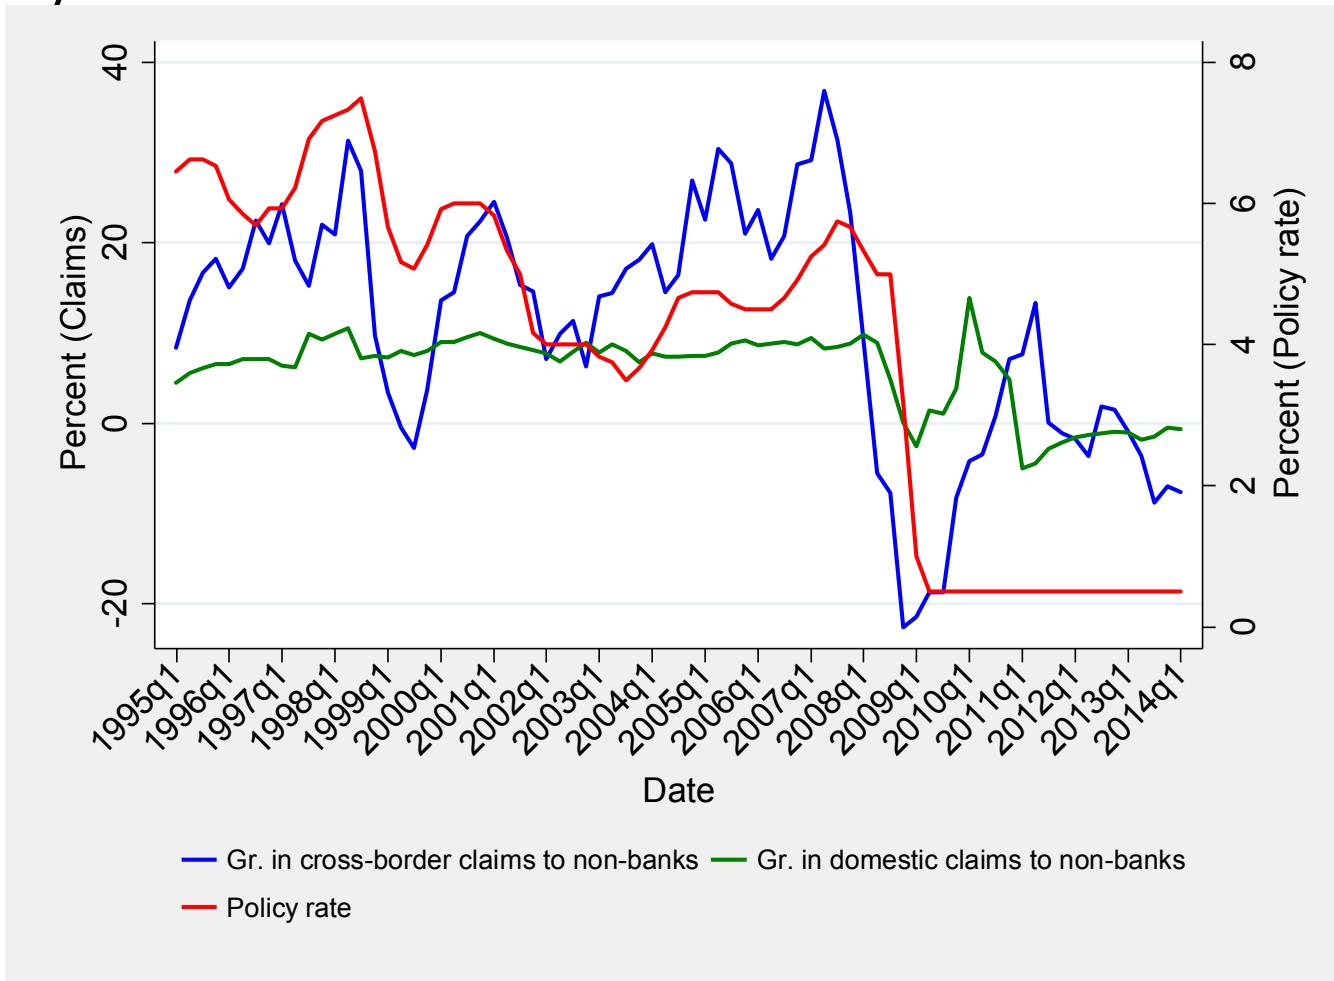

Main Findings

- The supply of cross-border bank flows increases with the monetary policy rate in the country of origin (in contrast to the traditional bank lending channel).
- When the monetary policy rate in the country of origin rises (relative to other countries), there is a portfolio rebalancing effect (Den Haan, Sumner and Yamashiro, 2007): banks' cross-border claims grow faster than domestic credit.
- When monetary policy rates increase, cross-border bank flows are mainly directed toward advanced economies and investment grade countries.

Data - BIS Locational Banking Statistics (LBS)

- Sample: 1995Q1 – 2014Q1

- Outliers: exclude country pairs if outstanding bilateral is below \$5 million in any quarter

U.K. bank flows to non-banks and the monetary policy rate

Does the reporting country's monetary rate affect cross-border bank flows?

$$Y_{ijt} = \gamma_{jt} + \alpha r_{it-1} + \beta X_{it-1} + \varepsilon_{ijt}$$

Where:

- r: nominal monetary policy rate for reporting country
- X: vector of control variables for the reporting country
- γ_{jt} : counterparty country x time fixed effects (controls for changes in the demand for bank flows)
- i: reporting country
- j: counterparty country
- t: time (quarterly frequency)

Identification

- The policy rate is a good reflection of the overall policy stance (Bernanke and Mihov, 1998).
- We identify the effect of the relative, to other reporting countries, monetary policy stance on cross-border flows.
- Is the policy rate exogenous to cross-border bank flows?
 - Central banks adjust monetary policy to achieve their mandate of price stability, and in some cases, maximum employment.
 - Cross-border bank flows are important for monetary policy if they are a threat to financial stability (reporting country) or if they have a significant effect on global output growth.
 - We consider these as second-order effects for a central bank's monetary policy reaction function.

Why do we care?

- Cross-border bank flows may be a risk to financial stability for those countries receiving the flows.
- It is important to assess whether monetary policy actions lead to changes in bank flows that potentially could affect foreign economies.
- There is pressing need to understand the interaction between monetary policy and financial stability, as it has implications for the use of macroprudential policies.
