Federal Reserve Board

Cathérine Koch  
Bank for International Settlements

Hyun Song Shin  
Bank for International Settlements
Key Results

1. Time Series: A stronger USD is correlated with larger deviations from CIP
2. Cross-section: Currencies with larger beta of CIP deviation to USD strength, are those with larger CIP deviations in the cross section
3. The result holds also for EUR

Interpretation: “USD is a proxy for a global risk factor: shadow price of bank leverage.”

Provider of Liquidity?
The EURUSD Basis and the EURUSD

- Significant contemporaneous correlation (at daily level) of EURUSD FX and the Basis
- Stronger USD -> Bigger Basis -> Synthetic USD becomes more expensive
Result #1 (Time Series)

- **Specification:**
  \[
  \Delta x_{it} = \alpha_i + \beta \Delta Dollar_t + \gamma \Delta BER_{it} + \delta \text{CONTR}_{it} + \varepsilon_{it}
  \]

  - **Dollar** = USD Trade-weighted index (USD and basket)
  - **BER** = Bilateral Exchange Rate (USD and country-i)
  - **CONTR** = lnVIX, FX-Vol(USD-i), etc..

1. **Global** USD appreciation correlates with widening of CIP deviations.
2. **Bilateral** USD appreciation is not important.
3. The result holds at daily frequency
4. 100bp of USD appreciation -> 2.1bp of CIP widening

Economic Significance (D)

- The result is super interesting!
- Caveat: The economic significance is not massive
  In 2011, the CIP Basis changed by 70bp in 7 months, while the FX by 8%  
  $8 \times 2.1bp = 16.8bp$ (vs. 70bp)
- Still, the result is certainly interesting
- Even more important is the lack of importance of the bilateral exchange rate
Economic Significance (Q)

The economic significance is halved at quarterly frequency. Moreover, at this frequency the country specific effect (*BER*) matters.

Result #2 (Cross-Section)

• First, estimate a CIP beta: \[ \Delta x_{it} = \alpha_i + \beta_i \Delta Dollar_t + \epsilon_{it} \]

• Is there a cross-sectional pattern between CIP and Beta?

This is a fascinating result. However,

– You use contemporaneous variations. The results could be just mechanical. By definition \( \beta_i = \Delta x / \Delta USD \), countries with the largest changes in the Basis are those with the largest beta (contemporaneously). You should do this similarly to Fama-MacBeth.

– Also, a formal test is missing.
Result #3 (Role of Banking Frictions)

- Is a strong USD negative news for banks equity (relative to their index?

</tr>
</tbody>
</table>

Notes: In all three columns, the dependent variable is the quarterly equity return in local currency. The independent variables are $\Delta Broad_t$, quarterly change in the broad dollar index ($\Delta Broad_t > 0$ indicates broad appreciation), $\Delta Broad_t \times bs_t$, the interaction between the broad dollar movement and the 5-year cross-currency basis, and $\Delta Market_t$, quarterly benchmark equity index return. All regressions include bank fixed effects and use robust standard errors clustered by banks, ***$p < 0.01$, **$p < 0.5$ and *$p < 0.1$.

- Column 1: +1% USD appreciation -> -2% in bank equity.
- Column 2: After controlling for Market, -0.2% return. Very small
- Column 3: The results survives for countries with large Basis
• Interpretation:
  – AUD and CAD have bank equities that are insensitive to USD fluctuation and positive basis.
  – DKK and CHF have bank equities that are very sensitive to USD and very negative basis.
Why does it matter?

- Main hypothesis: Stronger USD, lower bank lending in USD. The channel that generates CIP deviations is *global* bank lending friction.
- The friction is currency specific, it is *not country* specific.

Currency (i.e. *Global*)

or

Country Specific (i.e. *Local*) Explanation?

More Insights from the Cross-Section
DOLLAR FUNDING AND THE LENDING BEHAVIOR OF GLOBAL BANKS

VICTORIA IVASHINA
DAVID S. SCHARFSTEIN
JEREMY C. STEIN

First draft: October 2012
This draft: March 2015
CIP: Currency or Country Specific?

- Let’s focus on USDEUR, but consider sovereign bonds issued by different countries.

\[ Basis^*(t, T + t) = \frac{F_{t,T+t}}{X_t} (1 + R_{t,T+t}^a) - (1 + R_{t,T+t}^b) + \frac{F_{t,T+t}}{X_t} S_{t,T+t}^a - S_{t,T+t}^b. \]

- The Total basis is due to: (1) FX CIP violation, plus (2) Bond specific Basis.

- We know that FX CIP is violated, but how large is the contribution of the bond specific (country, instead of currency) component?

- Let’s focus on the country specific component, instead of the currency component.

- This allows us to investigate the importance of the “USD channel” versus “Country specific” funding structure (like different currency exposures)
Implementation via Asset Swap

- **EXAMPLE.** Brazil issues two bonds maturing on March 7 2015, one denominated in USD and one in EUR.

- Take the 7.375% Eur bond and do an asset swap to convert into Usd cash flows using traded FX forward strips. This creates a synthetic Usd-denominated bond.

- If cash flows were identical, LOP applies.

- We match the face value, the coupon stream do not match exactly. Thus, we define:

  \[
  Basis = Yield(B_{usd}) - Yield(\mathbb{S} \circ B_{Eur})
  \]

- The difference in the two bond spreads is equal to the cost of hedging the FX risk.
The Geography of the Basis

- The sign of the Basis is different even keeping the currency pair constant:
- Example: the correct strategy for the trader is:
  - Turkey — Long USD bonds and Short Euro bonds
  - Mexico and Brazil — Long Euro bonds and Short USD bonds
- Cannot be explained by a single common risk factor affecting all these markets at the same time.
Data on Geographical Exposure

• From BIS: detailed data on the geographical distribution of bank holdings:
  • All contractual lending by the head office, and all its branches (and subsidiaries) on a worldwide consolidated basis but disaggregated by country exposure.

  • We strip out all other forms of lending to focus exclusively on sovereign bond exposure.

  • The classification is based on “Ultimate Risk” (as opposed to “Immediate Borrower”). Namely, the country where the guarantor of the claim is located, or in other words, where the domestic bank head office is located. The exposures of the foreign branches and subsidiaries are included.

  • Example: a purchase by the Morgan Stanley London branch of Turkish bonds, for instance, contributes to the exposure of its U.S. head office.
Table 2
Banks holding exposure and international reserve distribution
Panel A displays the time evolution of the distribution of European and U.S. banks’ on-balance sheet exposure to Brazilian, Mexican, and Turkish aggregate amounts of external sovereign bonds based on “ultimate risk,” covering the sample from 2005 to 2010. Panel B displays the time evolution of the distribution of foreign asset values to total foreign assets for the Central Bank of Brazil (Banco Central do Brazil) and the Central Bank of Turkey (Turk Merkez Bankasi), covering the sample from 2004 to 2010. The reserve distribution data preceding 2008 are not available for Turkey. Foreign assets include the following currencies: the U.S. dollar (USD), euro (EUR), and others (e.g., Japanese yen (JPY), British pound (BGP), Canadian dollars (CAD), Australian dollars (AUD)).

Hypothesis

- Turkish Example: Turkish assets bonds are mostly funded by European balance sheets (2008Q4: 80% of claims were held in Europe vs. 11% in USA
- Brazil and Mexico: the opposite is true.

Main Message from Data:

1) Existence of a geographical dispersion in the funding markets of sovereign bonds.
2) Countries that rely more on funding from European (resp., American) banks are also those with higher cost of USD (EUR) financing, during the credit crisis.
3) During the crisis, the relative cost of funding through outside capital (unsecured commercial paper) versus inside capital (insured deposits) increases. That rise makes funding of USD-denominated assets by European banks increasingly expensive in comparison to euro-denominated assets.
4) The opposite holds for American banks, which then find funding euro-denominated assets more expensive than funding dollar assets.
Summary

• Both papers are extremely interesting and well written
• They highlight two slightly different channels/frictions that may give rise to CIP deviations
• More should be done in terms of understanding the Geography of Risk Capital and to distinguish currency vs. country specific channels
• Both papers will be very influential.
