

Nowcasting during the Pandemic:

Lessons from Argentina¹

E. Blanco (BCRA,UBA)

Ongoing project, preliminary results

- **Objective**: Evaluate Nowcasting performance during the COVID-19 pandemic of 2020
- **Methodology**: Dynamic Factor model
 - Different estimation schemes
 - Explore new high frequency data sets
- **Main Results**:
 - Good Nowcasting performance
 - Keeping parameters fixed makes no difference
 - Gain in using energy consumption

1. General Context: Lockdown in Argentina

2. Our Nowcast Exercise

2.1. DFM

2.2. Evaluating models' relative predictive ability

3. Empirical Results

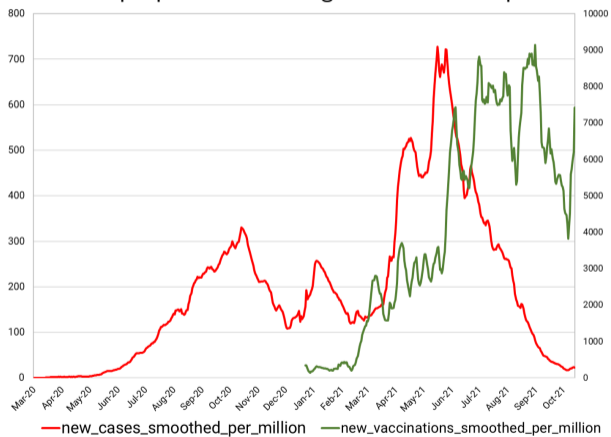

3.1. Estimation Scheme

3.2. Nowcasting using new data sources

4. Concluding Remarks

- Mandatory lockdown imposed on 19 March 2020
- Three distinctive phases:
 - 3/20/2020 to 6/7/2020 strong offer and mobility restrictions
 - 6/8/2020 to 03/12/2021 a progressive relaxation later
 - 6/6/2021 return to a "new normal"

2. Our Nowcast Exercise

2.1. DFM

2.2. Evaluating models' relative predictive ability

3. Empirical Results

3.1. Estimation Scheme

3.2. Nowcasting using new data sources

4. Concluding Remarks

- Objective: producing early predictions of GDP growth based on the pandemic and containment sample period 2020:Q1 - 2021:Q2.
- Initial set of [112 high frequency](#) business cycle indicators
 - Study the time series properties: stationarity and seasonality
 - Transform when needed
- Given the updating scheme, we can obtain 6 early estimations of the GDP growth within each quarter
- Rolling pseudo-real-time one quarter ahead *Nowcast*
 - Following previous results (D'Amato et al 2015, Blanco et al 2018) we consider a smaller group of variables selected
- Last, we compare their relative forecasting ability using the Giacomini and White (2006) test
 - consider a simple AR benchmark

3. Empirical Results

3.1. Estimation Scheme

3.2. Nowcasting using new data sources

4. Concluding Remarks

- A vector X_t of n stationary monthly business cycle indicators $x_t = (x_{1t}, \dots, x_{nt})'$, with $t = 1, \dots, T$ can be explained by the distributed lags of q common latent factors plus n idiosyncratic disturbances which could eventually be serially correlated. The dynamic factor model (DFM) is therefore:

$$X_t = \lambda(L)f_t + e_t \quad (1)$$

$$f_t = \Psi(L)f_{t-1} + \eta_t \quad (2)$$

Where f_t is a vector $q \times 1$ of unobserved (latent) factors, the lag polynomial matrices $\lambda(L)$ and $\Psi(L)$ are $N \times q$ and $q \times q$, η is a $q \times 1$ vector of (serially uncorrelated) innovations to the factors. The i row of $\lambda(L)$ is called the *dynamic factor loadings* for the i th series, X_{it} , and the e_t are the idiosyncratic disturbances that are assumed to be uncorrelated with the factors in all leads and lags

- Given a target variable y_t (in our case log GDP growth), the objective would be to estimate $E(y_t|X_t)$

$$y_t = \beta_t X_t + \gamma_t y_{t-1} + \varepsilon_t \quad (3)$$

$$y_t = \beta(L)'f_t + \gamma(L)'y_{t-1} + \varepsilon_t \quad (4)$$

- If we define quarterly GDP as the average of monthly latent observations $y_t^Q = \frac{1}{3}(y_t + y_{t-1} + y_{t-2})$ and we obtain quarterly factors f_t^Q from these observations, we can use the following equation to obtain early estimates of GDP:

$$\hat{y}_t^Q = \beta(L)'f_t^Q \quad (5)$$

- We follow Banbura et al (2010) and Banbura and Modugno (2014) to estimate the factors
- Suppose that the errors idiosyncratic component e_t follows a independent univariate autoregression ($e_{it} = \delta_i(L)e_{it-1} + \nu_{it}$, with $\nu_{it} \sim N(0, \sigma_{\nu_i}^2)$)
- Defining θ as a vector that incorporates all the parameters of the model (the λ factors loadings, ε_t and σ_t)
- Once the joint model is set up in State-Space form, we estimate the parameters θ of the state space form by the Expectation Maximisation (EM) algorithm.

1. General Context: Lockdown in Argentina

2. Our Nowcast Exercise

2.1. DFM

2.2. Evaluating models' relative predictive ability

3. Empirical Results

3.1. Estimation Scheme

3.2. Nowcasting using new data sources

4. Concluding Remarks

Evaluates out of sample forecasts by conducting an exercise using rolling windows

1. Compares the predictive ability of parametric models, f_{Rt} and g_{Rt} , to generate forecasts of y_t conditional on the available information set \mathcal{F}_t
2. Using the R sample observations available at time t , a total of P_n forecasts which satisfy $R + (P_n - 1) + \tau = T + 1$ are generated (τ steps ahead)
3. A loss function is calculated $L_{t+\tau}(y_{t+\tau}, f_{R,t})$, that depends on both, the realization of the data and the forecasts
4. The hypothesis to be tested is:

$$H_0 : E [h_t (L_{t+\tau}(y_{t+\tau}, f_{R,t}) - L_{t+\tau}(y_{t+\tau}, g_{R,t})) | \mathcal{F}_t] = 0$$

5. In practice, the test consists on regressing the differences in the loss functions on a constant and evaluating its significance using the t statistic for the null of a 0 coefficient ($\tau = 1$).

1. General Context: Lockdown in Argentina

 - 2.1. DFM
 - 2.2. Evaluating models' relative predictive ability
- 3. Empirical Results**
 - 3.1. Estimation Scheme**
 - 3.2. Nowcasting using new data sources
4. Concluding Remarks

- We applied a rolling windows estimation scheme: parameters of the nowcasting model are updated as new data becomes available
- Siliverstovs (2021) forecasts based on the recursively estimated coefficients proved out to be much closer to the out turns of GDP growth in the 2nd and 3rd quarters of 2020 than those based on pre-COVID period coefficients

2. Our Nowcast Exercise
 - 2.1. DFM
 - 2.2. Evaluating models' relative predictive ability
3. Empirical Results
 - 3.1. Estimation Scheme
 - 3.2. Nowcasting using new data sources
4. Concluding Remarks

- The COVID-19 pandemic and the unprecedented global sudden stop of 2020 posed a mayor challenge for traditional forecasting tools used in many central banks
- We evaluate a DFM nowcasting tool for Argentina during the lockdown and health crisis of 2020 and 2021 (sample period 2020:Q1 - 2021:Q2)
 - The impact of the shock in Argentina's economy was quite significant: largest annual fall in GDP since the 2002 economic crisis. Downturn of 2020 Q2 was the single biggest recorded
- Our exercise was able to capture the sign and magnitude of the q.o.q s.a. variation in GDP
 - It also outperforms an AR benchmark

- Re-estimation or keeping the models parameters fixed to a pre-pandemic level? **indistinguishable**
- Finally we explore a couple of new high-frequency data sources.
 - Energy consumption added as a separate regressor appears to improve nowcasts
 - Google Mobility index do not necessarily lead to a better assessment of the business cycle
- Future research agenda: exploring other high-frequency variables (i.e. financial data) and working with a methodology that allows for mixed data frequencies.

Thank you for your attention!
