Main Results
Definition of package tours for BOP compilers

The Directive EU 2015/2302 gives an official definition of package tours for the consumer protection as a combination of at least two different types of travel services for the purpose of the same trip (or holiday).

a) carriage of passengers;
b) accommodation;
c) rental of cars, other motor vehicles;
d) any other tourist service (not included in a, b, or c).

AN OPERATIVE DEFINITION FOR BOP COMPILERS

The purchase of two or more services, of which at least one to be recorded under the Bop travel item, when it is known the total value of the services, but not the value of the single components.

The Bank of Italy frontier survey

The Italian Survey on International Tourism was conducted from by the Bank of Italy since 1995. Two distinct operations are carried out at each border point:

1. **COUNTING (1.0 million per year):** The counting aims at assessing the number and the nationality of the travellers, entering or exiting from Italy. As of October 2020, we are using also mobile phone data in the estimation process.

2. **INTERVIEWING (110,000 per year):** The interviewing (face-to-face) consists in questioning a sample of the travellers, after having approached and stopped them, in order to assess a number of basic classification characteristics of the traveller, the trip, the expenditures, and so on (answers are recorded in real time via tablet).
The Bank of Italy frontier survey

The Packages Tour in the survey
In the questionnaire is collected the total value of the package and the services purchased: international transportation, accommodations, restaurants, other transports, other services (museum, tours, shows, rented vehicles).

The Practical Issue
Allocating the total package value to the single services components (in math terms, estimating the percentage shares of each package component).

V. "ALL INCLUSIVE" TRIPS

12a. Can you tell us if your trip was "all inclusive", that is an organized tour or tour package which included expenses for two or more types of the following services: transportation, overnight accommodations, meals, other services?
- Yes .............................................................................. 1
- No................................................................. 2 → Question 13a.

12b. Which services were included in the tour package you bought?
- Transportation between Italy and abroad ...................... 1
- Transportation within your own country, between foreign countries or within foreign countries .................................. 2
- Transportation within Italy ............................................. 3
- Accommodations, with or without meals included .............................................................. 4
- Restaurants, cafés (and other meals taken outside your own accommodations) ...................... 5
- Other services (museums, shows, entertainment, tours, rented vehicles, etc.) .................. 6

12c. How did you buy your travel package?
- with a tour operator/travel agent from your own town or your company’s Recreational Association, other associations, social groups ............................................. 1
- with an online travel agency or using a hotel booking portal ............................................. 2
- using the destination’s tourism portal ............................................. 3
- other (please specify) ............................................. 4

63 IPS – Central Bank as producer of official statistics
The Bank of Italy frontier survey

The Packages Tour in the survey - (share of the packages tour)

About 20 per cent of the travelers has bought a tour package in an international travel in 2018

63 IPS – Central Bank as producer of official statistics
The old procedure: the donor method

The package is broken down in the different components, using the proportion of the “twins’ travelers, that have not purchased a package in their travelers. The traveler and his twins should have the same characteristics: country of residence, mean of transport, length of the stay, type of accommodation, and reason of the trip.

Example
Suppose that an international traveler has purchased, for 1,200 Euro, a tour package with three components: an international air ticket, an hotel abroad, and a car rent (always abroad). The proportion (mean) of the three twins is used to split the total amount in the single components.

The old procedure: the donor method

The package is broken down in the different components, using the proportion of the “twins” travelers, that have not purchased a package in their travelers. The traveler and his twins should have the same characteristics: country of residence, mean of transport, length of the stay, type of accommodation, and reason of the trip.

A TRADE-OFF
It is not always possible find an enough number of “twins” for realizing robust estimations, because of the high number of the constrains (characteristics).

Number of twins vs Similarity
A new ML approach

The basic idea is to find a predictive model relating the shares of expenditure for transportation, accommodation and other services to the other variables collected in the survey, such as the travellers’ socio-demographic characteristics, the country of origin/destination, the type of transportation and accommodation, the number of nights, and so on.

The predictive models are estimated separately for the resident (Italian travellers) and non resident (foreign travellers): in total 6 models.

Since these shares are unobservable for package tours, this model must be estimated using the travellers who have not purchased a tourist package.
A new ML approach

THE SAMPLE

Italian and Foreign travelers, that have bought at least two kind of services (international transport, accommodation, other services) without a package tour in the period 2010 – 2018.

More than 500.000 interviews.

The 80% of the sample is used for the training of the algorithm, and the remaining 20% for its validation.
A new ML approach

The share $Q$ of expenditure (Exp) for international transports, accommodation and other services, for the traveller $i$ at time $t$ is given by

$$Q_{i,t}^j = \frac{\text{Exp}_{i,t}^j}{\text{TOT}_{i,t}}$$

Where TOT is the sum of the three services considered

$$J=1,2,3 \text{ (International transport, Accommodation, Other Services)}$$

The share can be estimated considering many features (characteristic of the traveller)

$$Q_{i,t}^j = \beta_0^j + \beta_{TD}^j T_{Di} + \beta_{CO}^j CO_{i,t} + \beta_{SD}^j SD_{i,t} + \beta_{TC}^j TC_{i,t} + \beta_{AC}^j AC_{i,t} + \epsilon_{i,t}^j$$

$TD_i$ is a set of time dummies;
$CO_{i,t}$ is the country of origin (destination) of the foreign (Italian) traveller;
$SD_{i,t}$ is a vector of socio-demographic characteristics (number of travellers, gender and age, the job of the interviewed, the reason of the journey);
$TC_{i,t}$ are the transportation features (mode of transport: car, train, boat and plane, the transportation company, the class of the flight/boat);
$AC_{i,t}$ indicates a vector of accommodation variables (number of nights distinguished by the type of accommodation)
A new ML approach

Since the right-hand side variables of the equation includes many variables, it is useful to employ a regularisation method to automatically select the relevant features. One of the most common methods used in the machine learning literature is the Least Absolute Shrinkage and Selection Operator (LASSO)

\[
\min_{\beta_0^j, \beta_{TD}^j, \beta_{CO}^j, \beta_{SD}^j, \beta_{TC}^j, \beta_{AC}^j} \sum_{i,t} (Q_{i,t}^j - \beta_0^j - \beta_{TD}^j T_{D,t} - \beta_{CO}^j C_{O_{i,t}} - \beta_{SD}^j S_{D_{i,t}} - \beta_{TC}^j T_{C_{i,t}} - \beta_{AC}^j A_{C_{i,t}})^2 - \lambda^j \left( \|\beta_0^j\|_1 + \|\beta_{TD}^j\|_1 + \|\beta_{CO}^j\|_1 + \|\beta_{SD}^j\|_1 + \|\beta_{TC}^j\|_1 + \|\beta_{AC}^j\|_1 \right)
\]

The coefficients are put equal to zero if in the preliminary estimation (without the regularization) they are quite small.
A new ML approach: main results

Comparison of the out-of-sample predictive performance of the Donor and LASSO methods

The LASSO regression improves the results of the Donor Method (unbiased estimation, and smaller Variance and Mean Square Error).

Abstract:
In order to estimate the travel item of the Italian Balance of Payments (BoP), the Bank of Italy carries out an extensive border survey, collecting information about travel expenditures from a sample of resident and foreign travellers. The travel item covers an assortment of goods and services: in particular, according to the international standards, it includes local transport, i.e. transport within the economy being visited, but excludes international transport, reported in a separate BoP item. In the questionnaire of the survey a detailed breakdown of expenditures is asked, allowing the correct split between the travel and international passenger transport components. However, this breakdown is not available if these two items are purchased in a package tour with a single transaction. The unbundling of package tours is therefore needed for the correct compilation of the BoP. The present paper proposes a machine learning algorithm based on LASSO techniques to impute the components of package tours, improving the performance of the current procedure employed by the Bank of Italy.

Keywords:
Balance of payments; Travel; International transport; Linear regression; Donor method.

1. Introduction:

The Bank of Italy carries out an extensive border survey on International Tourism, designed to elicit the travel expenditures of a sample of resident travellers coming back to Italy from a trip abroad and of foreign travellers leaving Italy after a visit in the country. The main purpose of the survey is the estimation of the travel item of the current account of the Italian Balance of Payments (BoP). Travel is a relevant component of Italian economy: in 2018, foreign travellers’ expenditures in Italy were 41.7 billion (2.4 per cent of Italian GDP), while Italian expenditures abroad amounted to 25.5 billion (1.5 per cent relative to GDP).

Unlike most of the other service categories of the BoP, travel is a transactor-based component that covers an assortment of goods and services. On the one hand, as reported in the IMF Balance of Payments and International Investment Position Manual (2009), goods and services provided to visitors during their trips, that would otherwise be classified under another item (such as postal services, telecommunications, local transport, hire of equipment, or gambling), are included under travel. On the other hand, travel excludes goods for resale, which are included in general merchandise and the acquisition of valuables (such as jewellery), consumer durable goods (such as cars and electric goods) that are included in customs data when in excess of custom thresholds.

1 We thank Matteo Piazza, Alfonso Rosolia and Simonetta Zappa for helpful comments and suggestions. The views expressed in the paper are those of the authors and do not involve the responsibility of the Bank of Italy.
2 For the sake of brevity, in the rest of the paper, we might refer to resident travellers using the adjective Italian and we might use the term foreign for non-resident ones.
Moreover, according to international standards, travel includes local transport (i.e., transport within the economy being visited and provided by a resident of that economy), but excludes international transport, which is included in a specific BoP item. International passenger transport covers all services provided in international transports to non-residents by resident carriers, as a credit, and those provided to residents by non-resident carriers, as a debit. In the questionnaire of the survey a detailed breakdown is adopted, making a distinction between international and local transport, accommodation, meals, other services (museums, courses, concerts, etc.), and goods (shopping). However, this breakdown is not available for package tours, when two or more items of an international travel are purchased with a single transaction. In fact, with regard to this kind of trips, it is possible to know only the total value of the package and which services are included but the value of each service bought with the package is unknown. The unbundling of package tours, which account for more than 20% of the travel credits and debts in 2018, is therefore needed for the correct compilation of the BoP. Currently, the donor method is used to unbundle package tours: in fact, the package of a given traveller is broken down in its different components using the proportion of an average “twin” traveller, who has not purchased a package in his travel. In principle, the traveller and his twin should have the same characteristics: country of residence, mean of transport, length of the stay, type of accommodation and reason of the trip. However, it is difficult to find enough twins to have stable estimates according to all these features and, consequently, some constraints must be relaxed with the risk of introducing bias in the estimates. In order to overcome the limitations of the current procedure, it is necessary to model the relationship between the most important components of a package tour (transportation, accommodation, and other included services) and the characteristics of travellers and those of their trip. Moreover, it is worth to select the relevant features to be included in the model as explanatory variables in an efficient way. This paper proposes a Machine Learning (ML) approach to solve these two issues. Firstly, a linear relationship is supposed between the shares of expenditure in the three major components of a package tour and a huge set of explanatory variables derived from the border survey. Then, the relevant features are selected using a popular regularisation method in the ML literature, i.e. the Least Absolute Shrinkage and Selection Operator (LASSO) proposed by Tibshirani (1996).

A number of authors have studied the ability of the LASSO and related procedures to select the relevant features and recover the correct model. Examples of this kind of literature include Knight and Fu (2000), Friedman et al. (2001), Donoho (2006), Meinshausen and Bühlmann (2006), Zhao and Yu (2006), Bunea et al. (2007), Meinshausen (2007) and, more recently, Lee et al. (2016), Plan and Vershynin (2016), Dalalyan et al. (2017).

Our proposed algorithm is trained using the interviews of the travellers without a package tour: in fact, for these travellers we know both their characteristics (and the features of their travel) and the expenditures in the different items. Then, the algorithm is applied to travellers with a package tour in order to impute the value of the unknown components. The comparison of the LASSO and donor method shows that the LASSO approach clearly outperforms the latter method in terms of prediction accuracy. In fact, the LASSO exhibits a lower variance of the forecast error term and eliminates completely the systematic bias that affects the current procedure.

Moreover, the strength of the approach described in this paper is also in its ability to incorporate the potential effects of exogenous variables that may alter the expenditure behaviours of international travellers. This flexibility will allow to take into account the impacts of the recent COVID-19 pandemic in the unbundling procedure applied to the next waves of the tourism survey.

2. Methodology:
According to the descriptive evidence of the Bank of Italy’s border survey, the main issue related to the unbundling of package tours is the estimation of the value of three components: the carriage of international transport, the expenditures for accommodation, and the residual
component.\(^3\) A bias in the estimation of the first component has also an effect in the correct allocation of the monetary flows between two BoP components, i.e. travel and international transport: from the compiler perspective, the priority in unbundling package tours is therefore the correct estimation of the international carriage of passengers. According to the results of the border survey, the second important aspect is the correct estimation of accommodation in package tours, as almost all packages contain this component.

The current procedure adopted in the Bank of Italy is the donor method (or nearest neighbour approach). The value of the package of a traveller is split in its components using the shares of "similar" travellers, the so-called twins, who have purchased the same services without buying a package (for details see Introduction).

In order to overcome the limitations of the donor method, a ML algorithm is proposed which should be able to improve the results of the unbundling procedure by exploiting in a more effective way all the information contained in the international tourism survey. In fact, on one side, a parametric structure is imposed to the relationship between the shares of expenditure in the different package components and the characteristics of travellers and their trips; on the other, the most useful features for the estimation of these shares are automatically selected using regularisation techniques.

The basic idea is to find a predictive model relating the shares of expenditure for international transport, accommodation and remaining services to the other variables collected in the survey, such as the travellers’ socio-demographic characteristics, the country of origin/destination, the type of transportation and accommodation, the number of nights, and so on. Since these shares of expenditure are unobservable for package tours, this model must be estimated using the travellers who have not purchased a package tour: in fact, for this kind of travellers we can observe both the target variables (international transport, accommodation and other services) and the input variables (i.e., the characteristics of the travel and of the travellers). Then, the model can be applied to the travellers with a package tour in order to infer from their features the value of the different components of the package.

More precisely, it is possible to estimate the following relationship in which the share of expenditure of traveller \(i\) in item \(j\) (international transport, accommodation, other services) is explained by a set of features:\(^4\)

\[
q_{ijt} = \beta_0^j + \beta_{TD}^j TD_t + \beta_{CO}^j CO_{i,t} + \beta_{SD}^j SD_{i,t} + \beta_{TC}^j TC_{i,t} + \beta_{AC}^j AC_{i,t} + \epsilon_{ijt}
\]

where \(TD_t\) are time dummies; \(CO_{i,t}\) is the country of origin (destination) of the foreign (Italian) traveller; \(SD_{i,t}\) is a vector of socio-demographic characteristics, such as the number of travellers, distinguished by sex and age, the job of the interviewed, the reason of the journey (work, pleasure, other); \(TC_{i,t}\) are the transportation features, like the mode of transport (car, train, boat and plane), the transportation company, the class of the flight/boat; finally, \(AC_{i,t}\) indicates a vector of accommodation variables, such as the number of nights distinguished by type of accommodation. Equation (1) can be estimated separately for Italian and foreign travellers without a package tour.

Then, the model can be applied to travellers that have bought a package tour in order to impute the unknown expenditure shares from their characteristics. In fact, for this latter kind of travellers, we know the input variables and the total value of the package, but we ignore the expenditures for the different items. The imputed expenditure shares \(\hat{q}_{ijt}\) are calculated as the predicted values of equation (1), rescaled in order to guarantee that \(\sum_{j=1}^{3} \hat{q}_{ijt} = 1\) (ruling out the few cases of negative predicted values).

---

\(^3\) In the rest of the analysis, we decide to aggregate in this residual component the other services different from international transport and accommodation (i.e., food-serving services, local transport, other services not included elsewhere).

\(^4\) We have also tested a model in which the logit of the expenditure shares are regressed on the explanatory variables. However, this specification exhibits worse forecasting performance than the linear model presented in this section.
The underlying assumption of the procedure is that there are no systematic differences in the expenditure shares between travellers with a package tour and travellers without a package, once controlling for the observed characteristics included in equation (1). Unfortunately, this hypothesis cannot be tested directly with the available data. However, it is important to stress that this assumption does not impose the equality between the total value of a package and the sum of the values of the different components if purchased separately; in fact, these two values are likely to be different due to agency costs or discount strategies. The assumption is violated only if the expenditure shares in the different items are different between package and standard tours, which is a far less restrictive hypothesis.

For the training and validation of the proposed algorithm, the Bank of Italy’s data of the International Tourism Survey are employed. In particular, it is worth to consider the interviews of the Italian and foreign travellers without a package tour that have sustained all the three types of expenditures (international transport, accommodation and the residual component) during their journey. The interviews carried out in the 2011-2018 period are used ending up with a repeated cross-section database: the total number of observations are 216,974 for Italian and 294,636 for foreign travellers. The 80% of the sample is used for the training of the algorithm, i.e. for the estimation of the model (hyper-)parameters, and the remaining 20% for its validation, comparing the observed expenditures with the ones predicted by the model.

Since the right-hand side of equation (1) includes many variables, especially dummies (e.g., one dummy variable for each month and year of the interview, country of origin/destination, transportation company, etc.), it is useful to employ a regularisation method to automatically select the relevant features. One of the most common methods used in the ML literature is the Least Absolute Shrinkage and Selection Operator (LASSO). This approach adds the sum of the absolute values of the model coefficients to the sum of squared residuals to be minimised, forcing the coefficients of the irrelevant variables to zero. In formula, the coefficients are estimated in this way:

\[
\begin{align*}
\min_{\beta_0, \beta_{TD}^j, \beta_{CO}^j, \beta_{SD}^j, \beta_{TC}^j, \beta_{AC}^j} & \sum_{i,t} \left( Q_{i,t}^j - \beta_0 - \beta_{TD}^j T_{D,t} - \beta_{CO}^j C_{O,i,t} - \beta_{SD}^j S_{D,t} - \beta_{TC}^j T_{C,i,t} - \beta_{AC}^j A_{C,t} \right)^2 \\
& + \lambda \left( \|\beta_0\|_1 + \|\beta_{TD}^j\|_1 + \|\beta_{CO}^j\|_1 + \|\beta_{SD}^j\|_1 + \|\beta_{TC}^j\|_1 + \|\beta_{AC}^j\|_1 \right)
\end{align*}
\]

For larger values of \( \lambda \), more coefficients are forced to zero: the choice of the value for this hyper-parameter becomes therefore crucial. Following the literature, \( \lambda \) is chosen by minimising the out-of-sample Mean Squared Error (MSE) in a cross-validation exercise in which the training sample is divided in five subsets. With the data considered, the optimal \( \lambda \) is very small: this implies that many variables are relevant.

### 3. Result:

It is worth to compare the predictive performance of the proposed approach with the current donor method in order to understand if and how the new methodology can improve the unbundling of package tours.

Both methods are trained using the 80% of the sample and the remaining 20% is employed to compare the accuracy of predictions measured in terms of forecast bias, variance of the prediction errors and, combining these two dimensions, with the MSE. In particular, the out-of-sample forecast errors with method \( m \) (donor or LASSO) are defined as:

\[
(3) \quad e_{i,t}^{m} = (\text{Exp}_{i,t} - \text{TOT}_{i,t} \hat{Q}_{i,t}^m) \cdot w_{i,t}
\]

where \( w_{i,t} \) are the survey grossing-up factors. The bias, standard deviation (STD) and the Root Mean Squared Error (RMSE) of the forecasts are calculated using the error terms in expression (3). Table 1 shows the results of this comparison, distinguishing between Italian and foreign travellers, as well as different package components. The analysis is conducted on the overall time period, i.e., the years from 2011 to 2018, and by focusing on the more recent
four-year period 2015-2018, when there has been a significant growth of package tours, especially among foreign travellers.

Notes: Bias, STD and RMSE are in euro.

It is possible to observe that the proposed approach clearly outperforms the donor method in the forecast of the most relevant components of package tours, i.e., international transport and accommodation. In fact, the LASSO method exhibits systematically lower values of bias and standard deviation, both for Italian and foreign travellers: considering the RMSE, the reduction in percentage terms is around 20 per cent for international transport and 10 per cent for accommodation. Looking at the residual component, the new method shows an increase of the bias with respect the donor approach; however, this increase is more than compensated by the reduction of the forecast error variability: in fact, the RMSE of the LASSO approach is still lower than the one obtained with the donor method.

The reduction of the bias for the international transport and accommodation components means that the model imposed to the data by the LASSO approach seems quite reasonable. Moreover, the variability of the imputation errors is lower in the case of LASSO given that in this method we need to estimate a vector of parameters, while the donor approach is fully non-parametric. These considerations explain the reason why our proposed approach outperforms the existing one.

The comparison of the forecasts for the 2015-2018 period proves the robustness of the analysis: in fact, the improvements gained with the new algorithm, in terms of bias and variance reduction, are confirmed. It also suggests that the new approach will probably be capable to learn quickly possible changes in the structure of travellers’ expenditures, which might have happened after the COVID-19 pandemic. On the contrary, the donor method, using only partially the information in the interviews, might require a longer time and many waves to identify enough twins to produce unbiased estimates after the pandemic outbreak.
4. Discussion and Conclusion:
In this paper, a ML approach is proposed with the aim of overcoming the limitations of the current donor method. The new approach improves the existing one in two directions: firstly, it models explicitly the relationship between the different components of a package and the characteristics of travellers and their trips in a parametric framework; secondly, it adopts a regularisation method, i.e. the LASSO, to automatically select the relevant features for the estimation of the package components.

The comparison of the out-of-sample forecasting performance of the two methods reveals that the ML algorithm generally outperforms the donor method in terms of more precise and, above all, less biased predictions. The robustness of the ML approach, tested with a more recent sub-sample, is a further advantage in the production of reliable estimations in the presence of behavioural changes in travellers’ expenditures, which might have occurred after the COVID-19 pandemic.

It is important to stress that in the analysis carried out in this paper we have made some minor simplifications, such as considering the interviews with strictly positive expenditure shares in all the three components, i.e., international transport, accommodation, and other expenditures. In the (few) cases in which a package does not include all the three items, but only two of them, the observed expenditure will be used for the service excluded from the package, while the model equations for the other two components will be employed to obtain the predicted shares in order to impute the unobserved expenditures. Moreover, the residual component called “other services” in this paper includes different services, like local transport, food-serving services, other services not included elsewhere, that will require ad-hoc models in the practical implementation of the proposed approach.

Despite these minor considerations, the evidence produced in this work should be enough to convince BoP compilers on the usefulness of ML methods to improve the unbundling of package tours.
