How well-anchored are long-term inflation expectations?¹

Richhild Moessner² and Előd Takáts³

July 2020

Abstract

We study the anchoring properties of long-term inflation expectations in emerging and advanced economies, as a measure of monetary policy credibility. We proxy anchoring by how short-term expectations relate to long-term inflation expectations. We find that long-term inflation expectations are less well anchored in emerging than in advanced economies for the period 1996-2019. These findings do not significantly differ between before and after the global financial crisis or away from and at the effective lower bound. We also find that persistent deviations of inflation from target affect long-term inflation expectations in advanced economies. Yet, persistent deviations do not have a stronger impact at the effective lower bound. Moreover, we find evidence for asymmetry: higher than targeted inflation has a larger impact on long-term inflation expectations.

1. Introduction

In this paper we study how well-anchored long-term Consensus survey inflation expectations are, as a measure of monetary policy credibility. We compare developments between emerging market economies (EMEs) and advanced economies (AEs). We also study how these anchoring properties of long-term inflation expectations have changed since the global financial crisis and at the effective lower bound (ELB).

Anchoring of inflation expectations has been at the centre of the monetary policy debate (see eg Coeuré, 2019). Some major central banks have had inflation persistently below their inflation target since the global financial crisis, including during periods of relatively strong economic expansion since then. This has led to concerns whether central banks are able to achieve their inflation target, particularly during a downturn. Such concerns may have weakened the credibility of the inflation target, and thereby that of monetary policy. This, in turn, may have led to less well-anchored long-term inflation expectations.

We investigate these issues by examining survey based long-term inflation expectations.\(^4\) We investigate in two ways how well-anchored long-term inflation expectations are: First, we consider how short-term inflation expectations relate to long-term inflation expectations. Our hypothesis is that for well-anchored long-run inflation expectations, long-run expectations should not react to short-term expectations, since shocks affecting short-term expectations should not influence expectations over long horizons. Second, we explore how well-anchored long-term expectations are around the inflation target. The intuition is that even if long-term expectations are unresponsive to short-term expectations, they may still not be well anchored if they are significantly below or above the target. Our test is based on the notion that long-term inflation expectations are well-anchored if their deviation from the inflation target does not respond to the deviation of short-term inflation expectations from the target. Conversely, they are less

\(^4\) Alternatively, one could investigate market based measures of long-term inflation expectations. Market-based and survey-based measures of inflation expectations need not coincide. Market based measures are available at a higher frequency, therefore, they are better suited to examine short-term changes. In contrast, survey based measures are not affected by inflation risk and liquidity premia. Therefore, their investigation can proceed directly, without estimating inflation risk and liquidity premia separately. For a discussion of survey - versus market-based inflation expectations see Galati et al (2011).
well-anchored if the deviation of long-term inflation expectations from target responds more to the deviation of the short-term inflation expectations from the target.

We find that long-term inflation expectations are less-well anchored in EMEs than in AEs for the period 1996-2019, and that the degree of anchoring is not significantly different post-crisis or at the ELB. We also find that persistent deviations of inflation from target affect long-term inflation expectations in advanced economies, but that this effect is not stronger at the ELB. Moreover, we find evidence for asymmetry, with positive persistent deviations of inflation from target affecting long-term inflation expectations more than negative deviations for advanced economies. These results suggest that persistent deviations of inflation from target have the potential to de-anchor long-term inflation expectations and therefore warrant close monitoring by policymakers.

Our results suggest that long-term inflation expectations have remained well-anchored in advanced economies at the ELB, suggesting that central bank credibility has not been adversely affected by the ELB. For EMEs we do not find robust results regarding the effect of the ELB, probably since there have only been much fewer instances of reaching the ELB in EMEs than in AEs in our sample.

Our paper contributes to the literature on the anchoring of inflation expectations by considering the effects of short-term inflation expectations and of persistent deviations of inflation from target on long-term inflation expectations in a panel framework, separately for EMEs and advanced economies. In particular, we build on the works of Buono and Formai (2018), Yetman (2020) and Apokoritis et al. (2019) and complement their analysis, among others, by focussing on deviations from inflation targets. Thereby, we refine the interpretation of well-anchored expectations as not only stable but also

---

5 Mehrotra and Yetman (2018) consider another way to analyse the anchoring of inflation expectations using multiple-horizon fixed-event forecasts from Consensus surveys. They show that longer-term forecasts are better anchored than shorter-term forecasts. Ehrmann (2015) studies the anchoring of short-term inflation expectations (current and next calendar year fixed-event forecasts, ie varying from one to 23 months ahead) from Consensus surveys in ten inflation-targeting AEs until 2014, using the following measures: the dependence of inflation expectations on lagged realised inflation, disagreement among forecasters, and the revision of short-term inflation expectations in response to news about inflation. Based on these measures, he finds that under persistently low inflation, some disanchoring of short-term inflation expectations occurs compared to situations where inflation is around target. Given that Ehrmann (2015) only studies the anchoring of inflation expectations with short horizons (fixed-event expectations with varying horizons of one to 23 months ahead), his results are not comparable with our study of long-term inflation expectations (constant-horizon expectations 6-10 years ahead). The literature and monetary policymakers commonly consider the anchoring of long-term, not short-term, inflation expectations as a measure of monetary policy credibility, as we do in this paper.
around the inflation target. By contrast, Buono and Formai (2018) consider only inflation expectations, and Yetman (2020) and Apokoritis et al. (2019) only consider changes in inflation expectations, rather than deviations of inflation expectations from target. Moreover, while Buono and Formai (2018) and Apokoritis et al. (2019) consider regressions for individual economies, we use panel regressions for a large panel of advanced and emerging economies.

There is some recent evidence on the determinants of the anchoring of long-term inflation expectations in the group of advanced and emerging economies. IMF (2018) finds that inflation targeting has contributed to better-anchored long-term inflation expectations in EMEs.6 Kose et al (2019) find for a group of emerging and developing economies that inflation targeting, high central bank transparency, strong trade integration and a low level of public debt are associated with better-anchored long-term inflation expectations.7 Yetman (2020) finds for a combined sample of EMEs and advanced economies that inflation targeting has played a modest role in affecting the anchoring of long-term inflation expectations.8 Moreover, he finds that recent periods with low inflation are correlated with decreased effects of short-term on long-term inflation expectations, suggesting that longer-term expectations have remained well-anchored.

Evidence on the anchoring of long-term inflation expectations is also available for individual countries using survey-based expectations. Buono and Formai (2018) study the effects of short-term on long-term expectations from Consensus surveys, using time-varying parameter regressions. They find that after the global financial crisis long-term expectations have been well-anchored in the United States, and to a lesser extent in the United Kingdom. The find that in the euro area long-term expectations have been de-anchored shortly after the global financial crisis and again starting from 2014, and that in Japan de-anchoring is more pervasive during the sample period of 1989-2017. Using

---

6 IMF (2018) considers the following measures for the anchoring of long-term inflation expectations: absolute deviations in inflation forecasts from a target, the variability of inflation forecasts over time, the dispersion of inflation forecasts across individual forecasters, and the sensitivity of inflation forecasts to surprises about current inflation.

7 As a measure of the anchoring of long-term inflation expectations, Kose et al (2019) consider the reactions of long-term inflation expectations to domestic and global inflation surprises.

8 Yetman (2020) considers the effects of short-term on long-term inflation expectations since the 1990s.
micro evidence from a survey at weekly frequency, Apokoritis et al. (2019) find that long-term euro area inflation expectations remained well anchored at the ECB’s inflation aim.

Evidence on the anchoring of long-term inflation expectations is also available for individual countries using market-based expectations. Several studies found signs of less well-anchored long-term inflation expectations in the euro area around 2014, in the wake of the euro area sovereign debt crisis (Galati et al., 2018; Cecchetti et al., 2015). Natoli and Sigalotti (2018) find that the risk of less well-anchored inflation expectations in the euro area, as well as in the United States and the United Kingdom, increased in 2014 but decreased somewhat subsequently.9

Consistent with our results, several other recent studies using a range of measures of anchoring based on the responses of long-term inflation expectations to inflation surprises and to short-term inflation expectations, have found that inflation expectations are less-well anchored in EMEs than in AEs (see IMF, 2016; Kose et al, 2019; and Yetman, 2020).

The remainder of the paper is organised as follows. Section 2 introduces the data. Section 3 presents the benchmark specification and results, while Section 4 presents robustness results. Finally, Section 5 concludes.

2. Data

We analyse semi-annual time-series data for emerging and advanced10 economies over the period 1994H1–2019H1, in April and October each year (for CZ, HU, PL, RU and TR in March and September until 2014H1 each year due to the forecast data structure as explained below).

9 See also Scharnagl and Stapf (2015) for a study using distributions derived from inflation-linked options for the euro area.

We use long-term inflation expectations (6-10 years ahead) from Consensus surveys, as our dependent variable, taken in April and October each year (for CZ, HU, PL, RU and TR in March and September until 2014H1 each year), in percent. We also use short-term Consensus inflation survey expectations, one-year ahead, interpolated from monthly current-year and next-year Consensus surveys to create a constant horizon one-year ahead series, in percent;\(^{11}\) we take differences between the dates of the long-term Consensus surveys of April and October (for CZ, HU, PL, RU and TR between March and September until 2014H1) each year, in percentage points.

We study the effects of short-term inflation expectations from Consensus surveys on long-term inflation expectations from Consensus surveys, as a measure of anchoring. Short-term inflation expectations are at a constant horizon of one year ahead, obtained by interpolating current-year and next-year Consensus survey expectations in April and October (for CZ, HU, PL, RU and TR March and September until 2014H1) each year.

The raw data shows that interpolated long-term inflation expectations on average are very close to inflation targets (Table B2). However, there is some dispersion, which is larger for emerging economies than for advanced economies. Furthermore, there are some outliers, due to disinflationary programs. A key example is Turkey: long-term inflation expectations there were much below the current inflation targets in Q2 2002 (see minimum for long-term inflation expectations minus inflation target).\(^{12}\) As expected, short-term inflation expectations show a larger variance and follow the inflation target less closely.

We also study the effects of persistent deviations of inflation from target on long-term inflation expectations, using year-on-year changes in the consumer price index.

\(^{11}\) For short-term Consensus survey expectations, we interpolate between the current-year, \(\pi_{it}^c\), and next-year, \(\pi_{it}^n\), survey responses, in order to obtain constant-horizon one-year ahead short-term expectation, \(STinexp_{it}\), according to \(STinexp_{it} = (1 - m/12) \cdot \pi_{it}^c + m/12 \cdot \pi_{it}^n\), with \(m = 1, \ldots, 12\), and \(m = 1\) for January, \(m = 2\) for February etc.

\(^{12}\) As these inflation targets were transitory, we check that our results remain robust when these observations are excluded.
3. Method and results

As a measure of the anchoring of long-term inflation expectations we consider the effects of deviations of short-term inflation expectations from target on deviations of long-term inflation expectations from target. Long-term inflation expectations are better anchored if they respond less to short-term inflation expectations. This measure can be estimated from the panel regression in equation (1):

\[
(LTinfxp_{it} - IT_{it}) = \alpha_i + \beta_t + \delta(LTinfxp_{it-1} - IT_{it-1}) + \gamma(STinfxp_{it} - IT_{it}) + \epsilon_{it} \quad (1)
\]

Here, \(LTinfxp_{it}\) denotes long-term inflation expectations in country \(i\) in period \(t\); \(t\) denotes the semi-annual period, since the long-term Consensus surveys are conducted semi-annually, in April and October each year (for CZ, HU, PL, RU and TR in March and September until 2014H1 each year); \(STinfxp_{it}\) denotes short-term inflation expectations in country \(i\) in period \(t\); and \(IT_{it}\) denotes the inflation target in country \(i\) at time \(t\).

The dynamic specification captures the persistence of long-run inflation expectations (with parameter \(\delta\) capturing the degree of persistence). We also include country fixed effects (\(\alpha_i\)) to control for any observed or unobserved time-invariant country heterogeneity. We apply time fixed effects to capture all potential global effects, such as oil price changes. We estimate equation (1) separately for inflation targeting advanced and emerging economies. We use within-group fixed effects panel regressions in our benchmark specification. The estimation period is 1994H1–2019H1.

The results of equation (1) show that long-term inflation expectations are less-well anchored in EMEs (Table 1, column 1) than in advanced economies (column 2). This is consistent with the results of IMF (2016), Bems et al (2018), Kose et al (2019) and Yetman (2020). We then turn to investigate whether the reactions of long-term inflation
expectations to short-term inflation expectations changed post-crisis. To do so, we consider a dummy variable for the post-crisis period, post, which equals one during 2009H2-2019H1, and zero otherwise, and estimate the following:

\[(LTinflation_{it} - IT_{it}) = \alpha_i + \beta_t + \delta(LTinflation_{it-1} - IT_{it-1}) + \gamma(STinflation_{it} - IT_{it}) + \gamma_D(STinflation_{it} - IT_{it}) \ast post_t + \epsilon_{it} \]  

(2)

The results of equation (2) are also shown in Table 1. We find that the degree of anchoring is not significantly different post-crisis for both EMEs (column 3) and advanced economies (column 4).

We next investigate whether the incidence of the ELB has affected the reactions of long-term inflation expectations to short-term inflation expectations. We consider dummy variables for the ELB, ELB_{it}, which equal one in country i at time t if the policy rate is less than or equal to 0.5 percent, and zero otherwise. We estimate

\[(LTinflation_{it} - IT_{it}) = \alpha_i + \beta_t + \delta(LTinflation_{it-1} - IT_{it-1}) + \gamma(STinflation_{it} - IT_{it}) + \gamma_D(STinflation_{it} - IT_{it}) \ast ELB_{it} + ELB_{it} \ast \epsilon_{it} \]  

(3)
The results of equation (3) are shown in Table 2. We find that the degree of anchoring is not significantly different at the ELB for both EMEs (column 3) and advanced economies (column 4). Our results suggest that long-term inflation expectations have remained well-anchored in advanced economies at the ELB, suggesting that central bank credibility has not been adversely affected by the ELB.

Standard errors are in parenthesis

*** p<0.01, ** p<0.05, * p<0.1

We then turn to estimate the effects of persistent deviations of inflation from target on long-term inflation expectations, according to equation (4):

\[
(LTinfexp_{it} - IT_{it}) = \alpha_i + \beta_t + \delta(LTinfexp_{it-1} - IT_{it-1}) + \gamma SStinfexp_{it} + \\
\mu(Inf_{ny} - IT_{ny})_{it} + \epsilon_{it}
\] (4)

Here, averages of deviations of inflation from target, \((Inf_{ny} - IT_{ny})_{it}\), are taken over n=2, 3, 4 or 5 years, starting with t-1. We control for \(SStinfexp_{it}\), changes in short-term inflation expectations.

The results of equation (4) are shown in Table 3. We find that persistent deviations of inflation from target statistically significantly affect long-term inflation expectations in advanced economies. These results remain in all investigated persistence time horizons:
two years (column 2), three years (column 4), four years (column 6) and five years (column 8). For emerging markets, the effect is only significant at the three-year horizon (column 3) due to larger standard errors. The coefficient estimates are similar to that of advanced economies, but the variance in EME data is substantially larger. Therefore, our results should not be seen as presenting conclusive evidence that persistent deviation from inflation targets have no effects in EMEs: it is possible that persistent deviations might affect long-term inflation expectations in EMEs as well. All in all, these results suggest that persistent deviations of inflation from target have the potential to de-anchor long-term inflation expectations and therefore warrant close monitoring by policymakers.

We also investigate whether there are asymmetric effects from persistent deviations of inflation from target, by estimating equation (5) below:

\[
(LT_{inf \ exp_t} - IT_{it}) = \alpha_t + \beta_t + \delta(LT_{inf \ exp_{t-1}} - IT_{it-1}) + \gamma \Delta ST_{inf \ exp_t} + \mu^+ (\text{Inf}_{ln_{ny}} - IT_{n_{ny}})_{+it} + \mu^- (\text{Inf}_{ln_{ny}} - IT_{n_{ny}})_{-it} + \epsilon_{it} \tag{5}
\]

Here, positive averages of deviations of inflation from target in country \( i \) at time \( t \) are denoted by \((\text{Inf}_{ln_{ny}} - IT_{n_{ny}})_{+it}\), and negative averages by \((\text{Inf}_{ln_{ny}} - IT_{n_{ny}})_{-it}\).
The results of equation (5) are shown in Table 4. We find evidence for asymmetry, with positive persistent deviations of inflation from target, i.e. higher than targeted inflation, affecting long-term inflation expectations more than negative deviations for advanced economies. These results suggest that positive persistent deviations of inflation from target have a greater potential than negative ones to de-anchor long-term inflation expectations, and therefore warrant particularly close monitoring by policymakers. The results also imply that current persistently lower than targeted inflation in some advanced economies might not be as concerning as some might have thought.

We next investigate whether the incidence of the ELB has affected the reactions of long-term inflation expectations to persistent deviations of inflation from target by estimating equation (6):

\[
(LTinf_{t} - IT_{t}) = \alpha_{t} + \beta_{t} + ELB_{it} + \delta(LTinf_{t-1} - IT_{t-1}) + \gamma\Delta Inf_{it} + \mu(Inf_{ny} - IT_{ny})_{it} + \mu(Inf_{ny} - IT_{ny})_{it} \ast ELB_{it} + \varepsilon_{it} \tag{6}
\]
The results of equation (6) are shown in Table 5. We find that the effect of persistent deviations of inflation from target is not significantly stronger at the ELB, for both EMEs and AEs.

Finally, we turn to study the stability of long-term inflation expectations irrespective of the level. Formally, we estimate the effects of changes in short-term inflation expectations on changes in long-term inflation expectations, according to equation (7):

$$\Delta LTinft = \alpha_i + \beta_t + \gamma \Delta STinft + \varepsilon_{it}$$  (7)
The results of equation (7) are shown in Table 6, separately for EMEs, AEs, and for inflation targeting EMEs and AEs. We can see that also on this measure long-term inflation expectations have been better anchored in AEs than in EMEs, consistent with the results above.

4. Robustness

We perform extensive checks to ensure the robustness of our results. First, we allow for interactions of positive and negative inflation deviations from target with the ELB (Table A1). The main motivation is to uncover whether the current coincidence of low rates and lower than targeted inflation in many advanced economies has special implications for the behaviour of long-term inflation expectations. We find that positive inflation deviations remain significant for AEs at most horizons (of three, four and five years), consistent with the results of Table 4. Negative inflation deviations tend to remain insignificant as well. Importantly, the interaction of the ELB with both positive and negative persistent deviations is not significant at any horizon for AEs. This result is consistent with the results (reported in Table 5) that the interaction of the ELB with persistent inflation deviations (not split into positive and negative ones) is insignificant at all horizons. Therefore, the results do not suggest additional concerns about the lower than targeted inflation levels in the current low rate environment. Yet, we should be

---

15 At the two-year horizon for AEs, the coefficient on positive inflation deviations decreases slightly and becomes insignificant, while the coefficient on negative inflation deviations increases slightly and becomes significant.
cautious about the interpretation: these results are based on historical data where the combination of low rates and low inflation was much less widespread than they are today.

Second, we re-estimate some results without Japan. The reason is that Japan experienced a very long period of low inflation and low interest rates with some country specific economic developments – and we would want to understand to which degree our broad results depend on a single country experience. In this context, first we re-estimate the interactions of positive and negative inflation deviations from target with the ELB estimated above in Table A1. The interaction of the ELB with both positive and negative persistent deviations remains insignificant at any horizon for AEs (Table A2). Thus, these interaction results are consistently insignificant irrespective of whether we include Japan or not. Next, we re-estimate without Japan the ELB interaction results when we do not distinguish between positive and negative deviations from inflation targets. We find that the earlier result shown in Table 5 that the interaction of the ELB with persistent inflation deviations is insignificant at all horizons is robust to excluding Japan (Table A3).

Third, we address concerns about high or transitory inflation targets. Some emerging markets, such as Turkey, used inflation targets during a period of disinflation to better anchor the policy transition. These transitory inflation targets might work differently than stable targets. Therefore, we re-estimate our main results (in particular Tables 1, 2 and 5) when excluding observations where the inflation target is greater than 10% (Tables A4, A5 and A6). The results (reported in Tables 1 and 2) that the interaction of deviations of short-term inflation expectations from the inflation target with the post-crisis dummy and with the ELB are insignificant for both AEs and EME remain robust to excluding observations where the inflation target is greater than 10% (Tables A4 and A5). Furthermore, the results (reported in Table 5) that persistent deviations of inflation from target in AEs are significant at all horizons of 2 to 5 years remain also robust (Table A6). Furthermore, the result that the interaction of persistent deviations of inflation from target with the ELB are insignificant in AEs also remain robust to excluding observations where the inflation target is greater than 10% (Table A6).

Fourth, we address concerns about the lag structure. Formally, we replace the one-period lag of the lagged dependent variable for deviations of long-term inflation
expectations from target in Tables 1 to 5 by a five-year lag, in order to remove any overlap of the horizon for the lagged long-term inflation expectations with the current long-term inflation expectations used as left-hand side variable (Tables A7 to A11). We find that when doing so, the coefficient on the lag of the dependent variable becomes smaller and insignificant at all horizons for both EMEs and AEs, as would be expected, but otherwise the results tend to remain similar. The coefficient on the interaction of deviations of short-term inflation expectations from target with the post-crisis dummy remains insignificant for both EMEs and AEs (Table A7), consistent with the results in Table 1, suggesting that long-term inflation expectations have not become better anchored after the crisis. The coefficient on the interaction of deviations of short-term inflation expectations from target with the ELB remains insignificant for AEs, again suggesting that long-term inflation expectations anchoring did not change at the ELB in AEs (Table A8). However, the coefficient on the interaction of deviations of short-term inflation expectations from target with the ELB remains negative and becomes significant for EMEs, suggesting that long-term inflation expectations became better anchored at the ELB in EMEs (Table A8). The coefficient on persistent deviations of inflation from target remains significant for AEs at all horizons (Table A9), consistent with the results of Table 3. The effects of positive persistent deviations of inflation from target remain significant for AEs at all horizons (Table A10), consistent with the results of Table 4. The coefficients on negative persistent deviations of inflation from target remain smaller than those for positive ones for AEs, but now become slightly larger and significant at horizons of two and three years (Table A10). Again, the ELB does not significantly affect the effect of persistent deviations of inflation from target for AEs (Table A11), consistent with Table 5.

Fifth, we replace the one-period lag of the lagged dependent variable for deviations of long-term inflation expectations from target in Tables 1 to 5 by a two-year lag. The results are shown in Tables A12 to A16. We can see that the results of Tables 1 to 5 are generally robust to this modification.

Finally, we check that the use of time fixed effects is not critical for our result by re-estimating the regressions in Table 1. Our coefficient estimates remain robust to the exclusion of time fixed effect (Table A17).
5. Conclusions

We studied the anchoring properties of long-term inflation expectations in emerging and advanced economies, as a measure of monetary policy credibility, by considering the effects of short-term expectations on long-term inflation expectations. We found that long-term inflation expectations are less-well anchored in EMEs than in AEs for the period 1996-2019, and that the degree of anchoring is not significantly different post-crisis or at the ELB.

We also found that persistent deviations of inflation from target affect long-term inflation expectations in advanced economies, but that this is not stronger at the ELB. Moreover, we found evidence for asymmetry, with positive persistent deviations of inflation from target affecting long-term inflation expectations more than negative deviations for advanced economies. These results suggest that persistent deviations of inflation from target have the potential to de-anchor long-term inflation expectations and therefore warrant close monitoring by policymakers, in particular for positive persistent deviations of inflation from target.

Our results suggest that long-term inflation expectations have remained well-anchored in advanced economies at the ELB, suggesting that central bank credibility has not been adversely affected by the ELB.

Previous volumes in this series

868  
June 2020  
Debt De-risking  
Jannic Cutura, Gianpaolo Parise and Andreas Schrimpf

867  
June 2020  
The effectiveness of macroprudential policies and capital controls against volatile capital inflows  
Jon Frost, Hiro Ito and René van Stralen

866  
May 2020  
Model risk at central counterparties: Is skin-in-the-game a game changer?  
Wenqian Huang and Elod Takáts

865  
May 2020  
The drivers of cyber risk  
Iñaki Aldasoro, Leonardo Gambacorta, Paolo Giudici and Thomas Leach

864  
May 2020  
Global and domestic financial cycles: variations on a theme  
Iñaki Aldasoro, Stefan Avdjiev, Claudio Borio and Piti Disyatat

863  
May 2020  
Pension contributions and tax-based incentives: evidence from the TCJA  
Ahmed Ahmed and Anna Zabai

862  
May 2020  
On the instability of banking and other financial intermediation  
Chao Gu, Cyril Monnet, Ed Nosal and Randall Wright

861  
May 2020  
Dealers’ insurance, market structure, and liquidity  
Francesca Carapella and Cyril Monnet

860  
April 2020  
Dollar invoicing, global value chains, and the business cycle dynamics of international trade  
David Cook and Nikhil Patel

859  
April 2020  
Post-crisis international financial regulatory reforms: a primer  
Claudio Borio, Marc Farag and Nikola Tarashev

858  
April 2020  
The Janus face of bank geographic complexity  
Iñaki Aldasoro and Bryan Hardy

857  
April 2020  
International bank lending and corporate debt structure  
Jose-Maria Serena and Serafeim Tsoukas

856  
April 2020  
Volatility spillovers and capital buffers among the G-SIBs  
Paul D McNelis and James Yetman

855  
April 2020  
Does the liquidity trap exist?  
Stéphane Lhuissier, Benoît Mojon and Juan Rubio Ramirez

854  
April 2020  
A new indicator of bank funding cost  
Eric Jondeau, Benoît Mojon and Jean-Guillaume Sahuc

853  
April 2020  
Home sweet host: Prudential and monetary policy spillovers through global banks  
Stefan Avdjiev, Bryan Hardy, Patrick McGuire and Goetz von Peter
