Global liquidity: selected indicators

Highlights

Indicators of global liquidity point to a continued strengthening of risk appetite and loosening of credit conditions in the spring and summer of 2014. International credit flow patterns in many regions have favoured growth in debt issuance over bank-intermediated cross-border funding. Since mid-September, some market jitters have reappeared, reflecting heightened geopolitical risks as well as market participants’ perception that the timing of the Federal Reserve’s exit from accommodative policy might be brought forward even as central banks in other advanced economies, particularly the euro area and Japan, have maintained or intensified easing measures. This shift in perceptions has resulted in an appreciation of the US dollar against a broad range of currencies, including an especially sharp depreciation in the case of some emerging market economies (EMEs), as well as falling equity markets and some widening of credit spreads. The strong dollar has put downward pressure on commodity prices, adding to the challenges facing commodity exporters.

The financing patterns of the past few years could expose markets to further vulnerabilities going forward as quantities and prices continue to adjust to shifts in monetary conditions and the macroeconomic outlook. While monetary policy remains highly accommodative in the major economies, diverging forward paths for monetary policies among the advanced economies and the implied changes in relative funding costs could set the stage for further significant market adjustments. The impact of these shifts on financing flows remains to be seen.

Whereas the previous edition of these indicators in March pointed to signs of a divergence between ongoing loose conditions in advanced economies and a more cautious stance in emerging market economies, in the months that followed conditions again loosened for the emerging economies. Among other things, this reflected: the strong policy reaction on the part of a number of EME authorities, which helped to stabilise these economies and restore market confidence; the easing of concerns that a rapid withdrawal of accommodation by the Federal Reserve would disrupt global financing patterns; ongoing search for yield in an environment of very low nominal rates; and the adoption of greater monetary accommodation, including quantitative easing measures, by the ECB.

Cross-border bank credit growth, which often accompanies upswings in global risk-taking, turned positive in the first quarter of 2014, with a quarter-on-quarter rise of $580 billion, after having fallen for several quarters. As a result, international bank credit (the sum of cross-border and local foreign-currency claims) through the first quarter of 2014 was flat on a year-on-year basis, after

---

1 This note provides an update of the BIS’s global liquidity indicators. For the conceptual framework behind the indicators, please see the appendix to the October 2013 update (available at http://www.bis.org/statistics/gli/gli_oct13.pdf).
several quarters in which this indicator had exhibited a year-on-year decline (Graph I.1). In contrast to bank lending, debt securities continued to gain importance as a channel for global credit flows through the first half of 2014 (Graph I.3). Bond markets have been especially prominent in flows to EMEs (Graph III.1). Strong issuance of emerging market debt instruments has been spurred by inflows into emerging market-oriented mutual funds (Graph III.1, bottom right-hand panel), which rebounded strongly in the first half of 2014 after a wave of outflows in late 2013. As discussed in the September 2014 BIS Quarterly Review (pp 17–18), much of this issuance took place through offshore vehicles; as a result, it is not fully picked up by statistics that classify issuance on a residence basis. The increased maturity of these issues reduces rollover risk, but may expose investors to greater losses if prevailing market yields rise or volatility in foreign exchange markets increases.

Long-term debt issuance has been supported by the decline in the term premium (Graph II.1). This premium (as modelled by the BIS) returned to negative territory in 2014 for both US and German government bonds, after approaching zero in the second half of 2013 ahead of the tapering of asset purchases by the Federal Reserve. The relatively low level of the premium on German bunds reflects the market’s shift of focus away from the Fed’s purchases and towards European disinflation as well as further easing by the ECB.

Specific observations

- Cross-border bank credit has grown especially strongly in the Asia-Pacific region (Graph I.2, bottom left-hand panel), though the stock of such credit in the region remains small relative to very large domestic credit stocks. Cross-border lending to borrowers resident in the US also rose in the first quarter, while remaining negative on a year-on-year basis, as domestic US bank credit accelerated (Graph I.2, top centre panel). Robust domestic bank credit growth has also offset consecutive declines in cross-border bank lending to Latin American economies. In contrast, both types of bank lending have been contracting in the euro area and emerging Europe, with a particularly pronounced decline in cross-border bank credit in the euro area.

- Despite having risen in the last few weeks, both implied and realised volatility generally remain low across a range of asset markets (Graphs I.1 and IV.1). That said, there have been signs of repositioning, especially in FX markets. Moreover, as discussed in the September 2014 BIS Quarterly Review (pp 10–11), a measure of risk aversion derived from comparing implied to realised equity volatility is still at historically low levels.

- The sharper declines in term premia on euro area debt compared to the US have been associated with a drop in the growth of US dollar-denominated offshore bond issuance, while euro bond issuance has been catching up (Graph I.3). This trend has been reinforced by the narrowing spread on cross-currency basis swaps (Graph III.3, bottom left-hand panel), which has reduced the incentive for borrowers to issue in dollars and swap the proceeds into euros.

- In the first half of 2014, loan-to-deposit and non-core liabilities ratios of European banks came down to levels not seen in a decade, while remaining above their US and Japanese counterparts. Both ratios continued to trend up in EMEs, though they remained below advanced economy levels (Graph III.2).
Through August, long positions in “high-yielding” currencies, such as the Australian and New Zealand dollars and Mexican peso, were funded by short positions in the euro, Swiss franc and Japanese yen (Graph IV.1). Some of these positions were reversed in September. Whether and how any carry trade positions will be unwound over the coming weeks will largely depend on the magnitudes of currency market volatilities and the ease of switching out of US dollar funding to funding in other currencies by banks and other financial intermediaries. Furthermore, to the extent that currency risk has been increasingly borne by non-financial borrowers, who tend to borrow directly in US dollars and other major low-yielding currencies, this may modify the dynamics of the adjustments going forward, for example if these borrowers exit these positions more rapidly than others.

Bank loans

Credit to non-residents:

Debt securities

Bank loans

Credit to residents

1 At constant end-Q1 2014 exchange rates.
2 Credit to non-financial sector in the United States/euro area/Japan from national flow of funds, excluding identified credit to these borrowers in non-domestic currencies (ie cross-border and locally extended loans and outstanding international bonds in non-domestic currencies).
3 Cross-border and locally extended loans to non-banks outside the United States/euro area/Japan. For China and Hong Kong SAR, locally extended loans are derived from national data on total local lending in foreign currencies on the assumption that 80% are denominated in US dollars. For other non-BIS reporting countries, local US dollar/euro/Japanese yen loans to non-banks are proxied by all BIS reporting banks’ gross cross-border US dollar/euro/Japanese yen loans to banks in the country, on the assumption that these funds are then extended to non-banks.

2 HFRI Monthly Performance Indices calculated by Hedge Fund Research; 12-month moving average.  
3 Carry-to-risk ratios reflect the attractiveness of carry trades by measuring the ex ante, risk-adjusted profitability of a carry trade position such that the one-month interest rate differential is divided by the implied volatility of one-month at-the-money exchange rate options. Aggregates for possible target currencies are obtained by averaging the relevant currency pairs.
